

13. Fenotipik Özelliklerin Evrimi

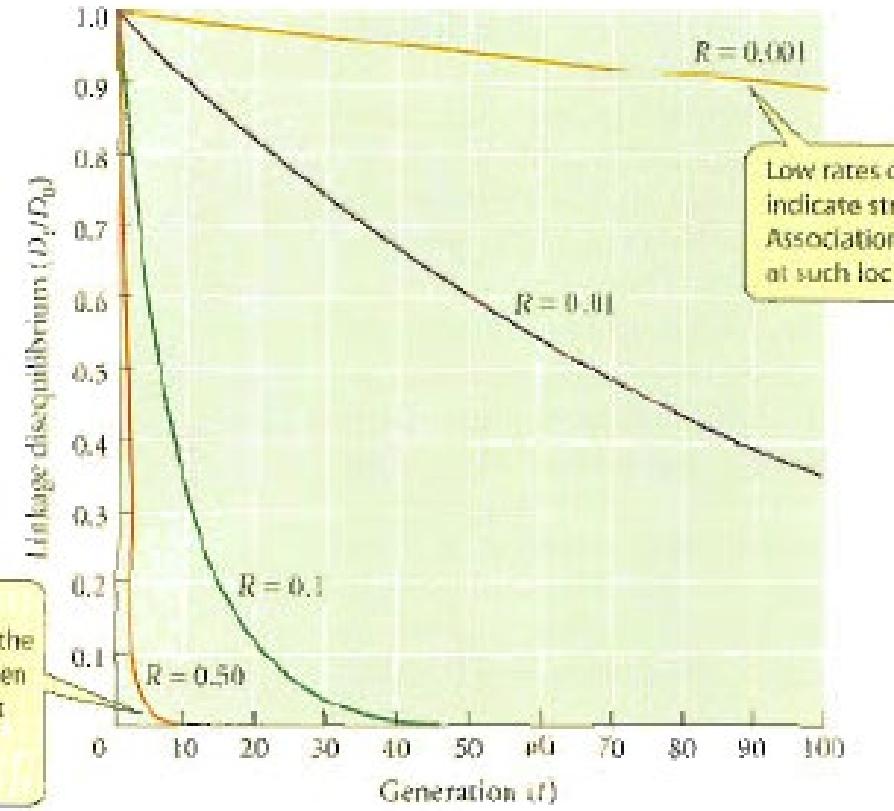

The phenotype variation among individuals with same genotype is the environmental variance

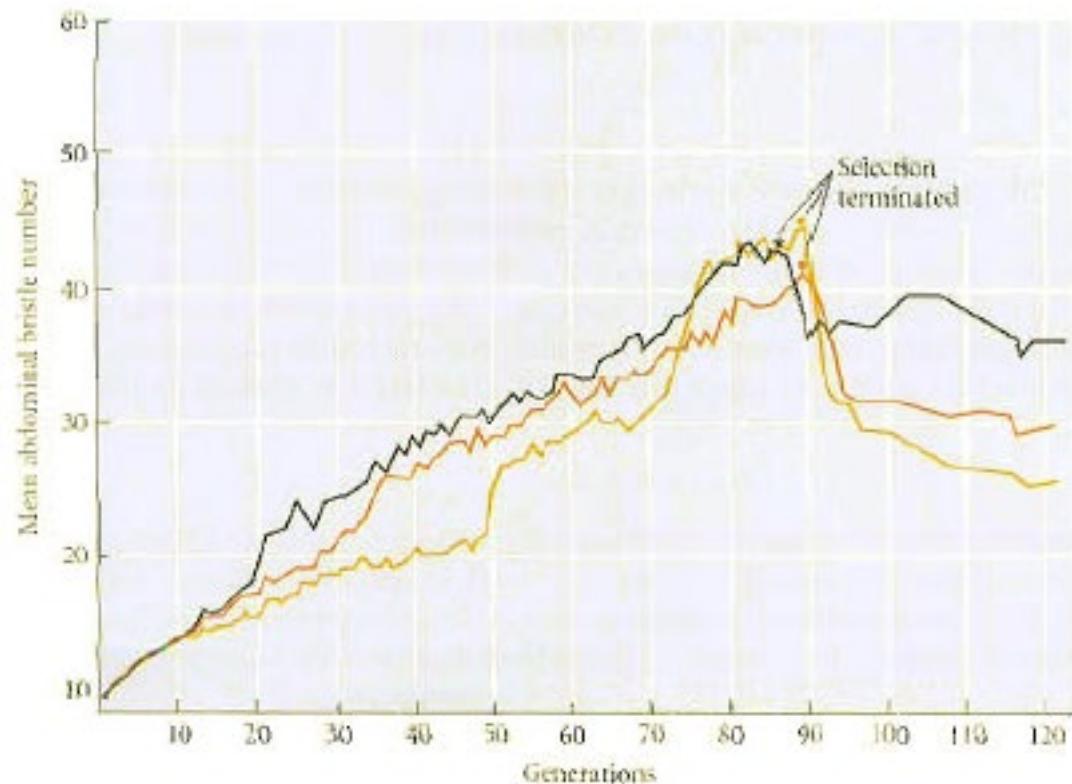

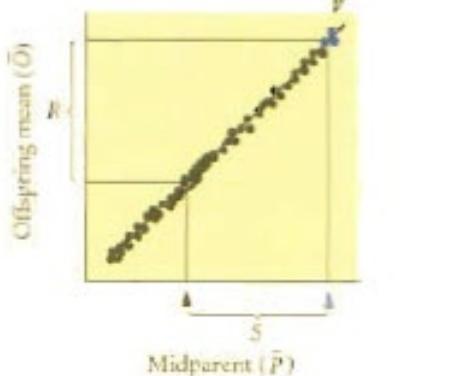

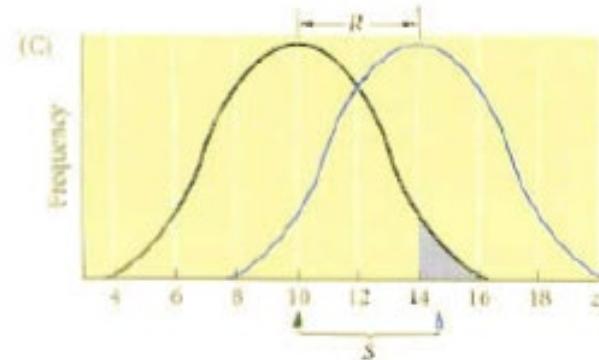

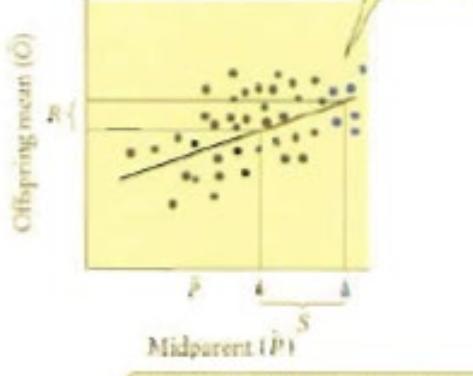

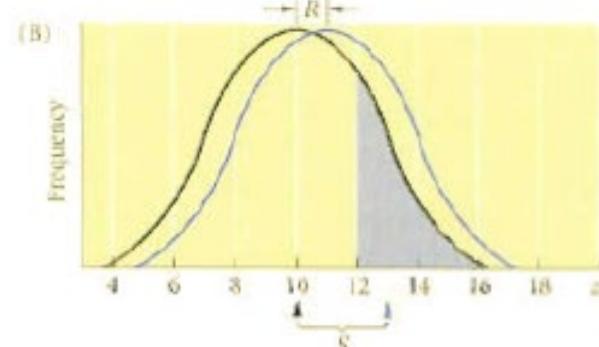

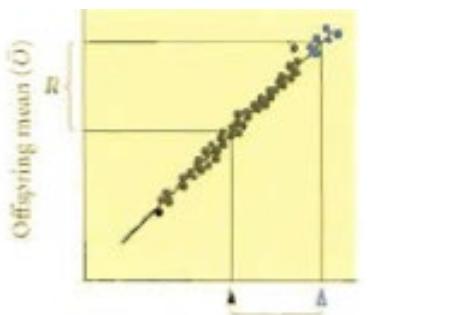

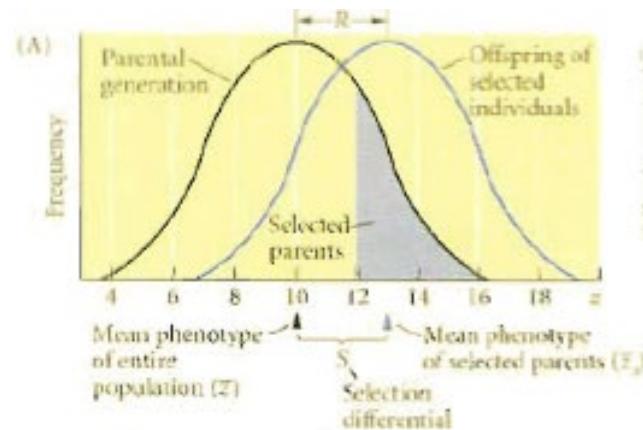

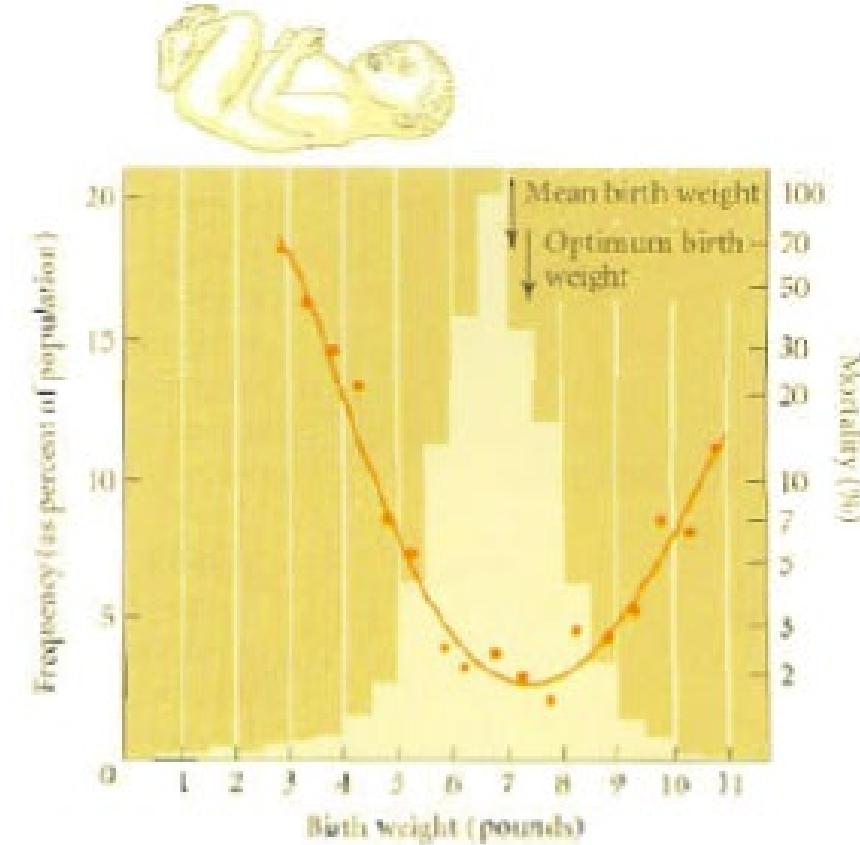

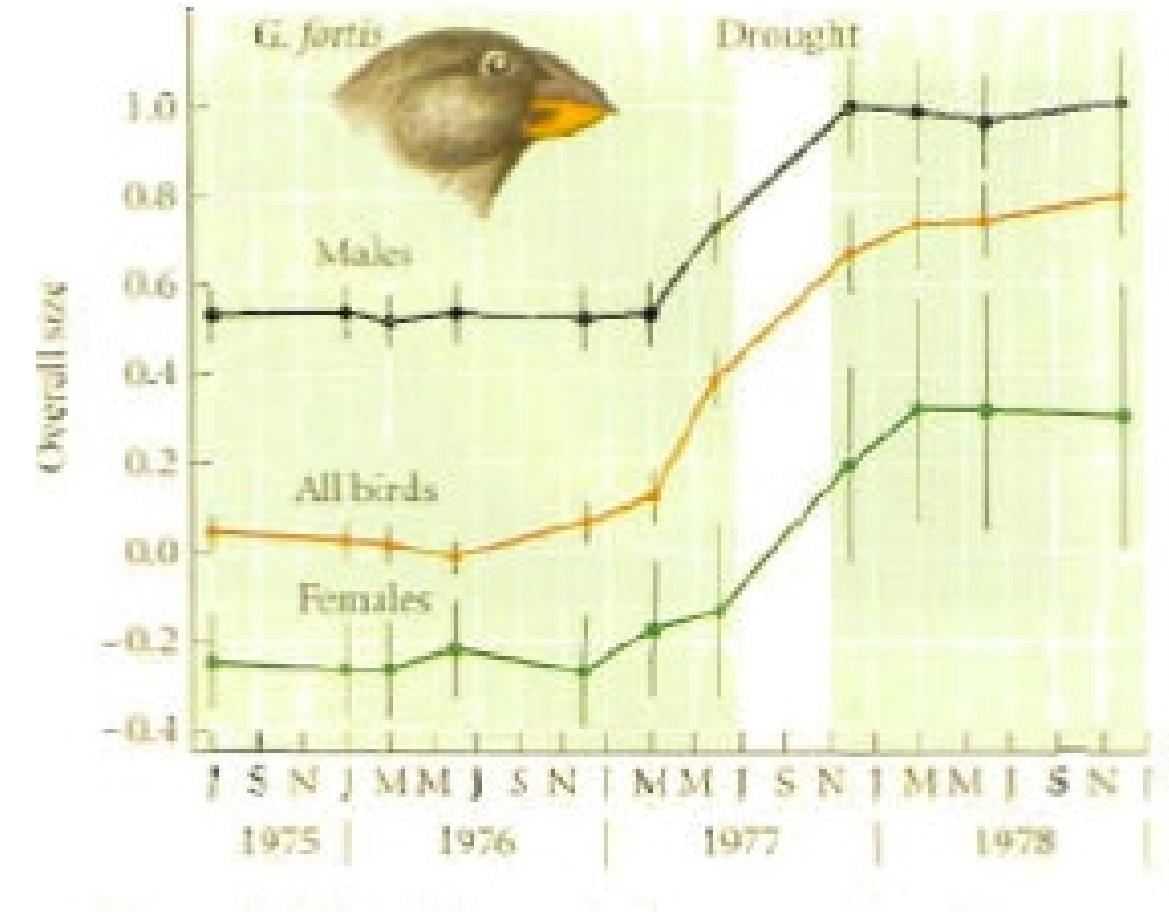

Chromosomes 3 of flies selected for:

When $R = 0.5$, loci are unlinked, and the association between alleles on different loci rapidly approaches zero.

(C)

If selection against eating leeches is stronger than selection for eating slugs, the genetic correlation of the two traits causes a temporary maladaptive aversion to slugs before the population eventually evolves to the optimum.

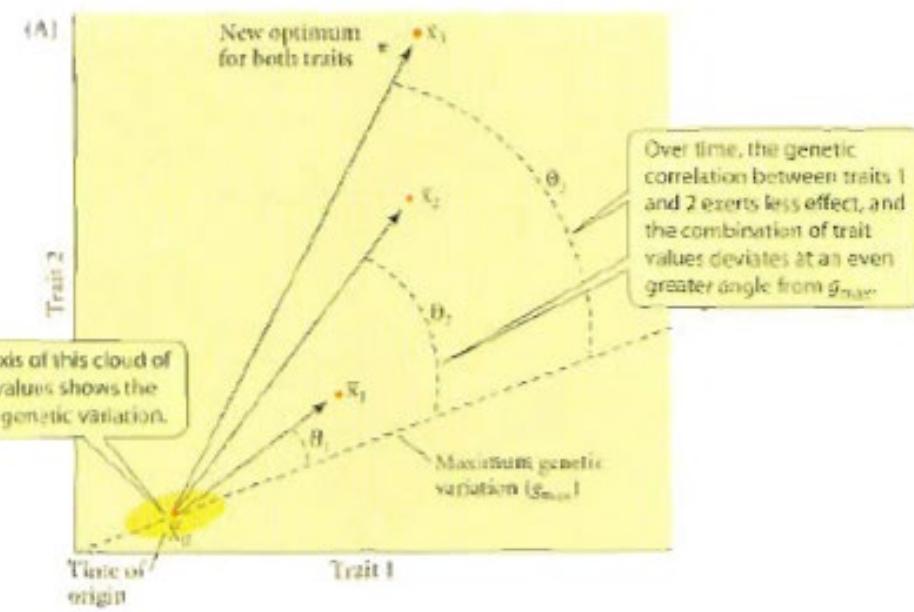

(D)

Mean fitness is highest for snakes that accept slugs but avoid leeches.

If selection for eating slugs is stronger than selection against eating leeches, the propensity to eat leeches may temporarily increase due to the positive genetic correlation.
