

# Space/Time Trade-Offs

Murat Osmanoglu

# Space/Time Trade-Offs

- solve a problem in less time by using more storage space, or in little space by spending a long time

# Space/Time Trade-Offs

- solve a problem in less time by using more storage space, or in little space by spending a long time
- you may have a large amount of space but not infinite, or you can wait a little more but not forever

# Space/Time Trade-Offs

- solve a problem in less time by using more storage space, or in little space by spending a long time
- you may have a large amount of space but not infinite, or you can wait a little more but not forever

## Space-for-Time Tradeoffs

- we cover two varieties of space-for-time algorithms:

# Space/Time Trade-Offs

- solve a problem in less time by using more storage space, or in little space by spending a long time
- you may have a large amount of space but not infinite, or you can wait a little more but not forever

## Space-for-Time Tradeoffs

- we cover two varieties of space-for-time algorithms:
  - input enhancement; preprocess the input to store the additional information to be used later to improve the time efficiency

# Space/Time Trade-Offs

- solve a problem in less time by using more storage space, or in little space by spending a long time
- you may have a large amount of space but not infinite, or you can wait a little more but not forever

## Space-for-Time Tradeoffs

- we cover two varieties of space-for-time algorithms:
  - input enhancement; preprocess the input to store the additional information to be used later to improve the time efficiency
  - pre-structuring; preprocess the input to make accessing its element easier

# Input Enhancement

## Sorting Problem

	Best Case	Average Case	Worst Case	Space
Selection Sort	$O(n^2)$	$O(n^2)$	$O(n^2)$	1
Bubble Sort	$O(n^2)$	$O(n^2)$	$O(n^2)$	1
Insertion Sort	$O(n)$	$O(n^2)$	$O(n^2)$	1
Merge Sort	$O(n \log n)$	$O(n \log n)$	$O(n \log n)$	$O(n)$
Quicksort	$O(n \log n)$	$O(n \log n)$	$O(n^2)$	$O(\log n)$

# Input Enhancement

## Sorting Problem

	Best Case	Average Case	Worst Case	Space
Selection Sort	$O(n^2)$	$O(n^2)$	$O(n^2)$	1
Bubble Sort	$O(n^2)$	$O(n^2)$	$O(n^2)$	1
Insertion Sort	$O(n)$	$O(n^2)$	$O(n^2)$	1
Merge Sort	$O(n \log n)$	$O(n \log n)$	$O(n \log n)$	$O(n)$
Quicksort	$O(n \log n)$	$O(n \log n)$	$O(n^2)$	$O(\log n)$

- What is common among all of these algorithms?

# Input Enhancement

## Sorting Problem

	Best Case	Average Case	Worst Case	Space
Selection Sort	$O(n^2)$	$O(n^2)$	$O(n^2)$	1
Bubble Sort	$O(n^2)$	$O(n^2)$	$O(n^2)$	1
Insertion Sort	$O(n)$	$O(n^2)$	$O(n^2)$	1
Merge Sort	$O(n \log n)$	$O(n \log n)$	$O(n \log n)$	$O(n)$
Quicksort	$O(n \log n)$	$O(n \log n)$	$O(n^2)$	$O(\log n)$

- What is common among all of these algorithms?

the sorted order they determine is only based on comparisons between the input elements

# Input Enhancement

## Sorting Problem

	Best Case	Average Case	Worst Case	Space
Selection Sort	$O(n^2)$	$O(n^2)$	$O(n^2)$	1
Bubble Sort	$O(n^2)$	$O(n^2)$	$O(n^2)$	1
Insertion Sort	$O(n)$	$O(n^2)$	$O(n^2)$	1
Merge Sort	$O(n \log n)$	$O(n \log n)$	$O(n \log n)$	$O(n)$
Quicksort	$O(n \log n)$	$O(n \log n)$	$O(n^2)$	$O(\log n)$

- What is common among all of these algorithms?

the sorted order they determine is only based on comparisons between the input elements

- Can we establish a lower bound on the number of comparisons for the worst case of comparison-based sorting algorithms ?

# Input Enhancement

## Sorting Problem

- Let's use a decision tree to get the intuition

a full binary tree that represents the comparisons between elements that are performed by the algorithm

# Input Enhancement

## Sorting Problem

- Let's use a **decision tree** to get the intuition

a full binary tree that represents the comparisons between elements that are performed by the algorithm

# Input Enhancement

## Sorting Problem

- Let's use a **decision tree** to get the intuition

a full binary tree that represents the comparisons between elements that are performed by the algorithm

# Input Enhancement

## Sorting Problem

- Let's use a **decision tree** to get the intuition

a full binary tree that represents the comparisons between elements that are performed by the algorithm

# Input Enhancement

## Sorting Problem

- Let's use a **decision tree** to get the intuition

a full binary tree that represents the comparisons between elements that are performed by the algorithm

# Input Enhancement

## Sorting Problem

- Let's use a **decision tree** to get the intuition

a full binary tree that represents the comparisons between elements that are performed by the algorithm

- for the input (4, 9, 6), the red path indicates the decision made

# Input Enhancement

## Sorting Problem

- Let's use a **decision tree** to get the intuition

- each permutation appears as one of the leaves in the tree

- for the input (4, 9, 6), the red path indicates the decision made

# Input Enhancement

## Sorting Problem

- Let's use a **decision tree** to get the intuition

- each permutation appears as one of the leaves in the tree
- the depth of a particular node will be the number of comparisons the comparison-based sorting algorithm performs

- for the input (4, 9, 6), the red path indicates the decision made

# Input Enhancement

## Sorting Problem

- Let's use a **decision tree** to get the intuition

- each permutation appears as one of the leaves in the tree
- the depth of a particular node will be the number of comparisons the comparison-based sorting algorithm performs
- the height of the tree then will equal to the worst-case number of comparisons

- for the input (4, 9, 6), the red path indicates the decision made

# Input Enhancement

## Sorting Problem

- Let's use a **decision tree** to get the intuition

- each permutation appears as one of the leaves in the tree
- the depth of a particular node will be the number of comparisons the comparison-based sorting algorithm performs
- the height of the tree then will equal to the worst-case number of comparisons

- let  $L$  be the number of leaves,  $h$  be the height of the decision tree, and  $n$  be the size of the input

- for the input (4, 9, 6), the red path indicates the decision made

# Input Enhancement

## Sorting Problem

- Let's use a **decision tree** to get the intuition

- each permutation appears as one of the leaves in the tree
- the depth of a particular node will be the number of comparisons the comparison-based sorting algorithm performs
- the height of the tree then will equal to the worst-case number of comparisons

- let  $L$  be the number of leaves,  $h$  be the height of the decision tree, and  $n$  be the size of the input

$$L = n!, L \leq 2^h$$

- for the input (4, 9, 6), the red path indicates the decision made

# Input Enhancement

## Sorting Problem

## Horspool's Algorithm

- use the pattern to make a 'Bad Match Table' that stores shift sizes of all possible characters
- compare the character  $c_0$  in the pattern with the character  $c_{n-1}$  in the text
- if a mismatch occurs, shift the pattern by the value in the table
- first, let's analyze the following cases (to determine the shift size, we look at the character that is aligned against the last character of the pattern):
  - if there is no **such character** in the pattern, we can safely shift the pattern by its entire length
  - if **the character** contained in the pattern but it is not the last one, the shift should align the rightmost occurrence of the character in the pattern with **the character** in the text

# Input Enhancement

## Horspool's Algorithm

- use the pattern to make a 'Bad Match Table' that stores shift sizes of all possible characters
- compare the character  $c_0$  in the pattern with the character  $c_{n-1}$  in the text
- if a mismatch occurs, use the value in the table to determine the shift
- first, let  $c$  be the character in the text (we look at the character that is aligned against the last character of the pattern):
  - if there is no **such character** in the pattern, we can safely shift the pattern by its entire length
  - if **the character** contained in the pattern but it is not the last one, the shift should align the rightmost occurrence of the character in the pattern with **the character** in the text

# Input Enhancement

## Horspool's Algorithm

- use the pattern to make a 'Bad Match Table' that stores shift sizes of all possible characters
- compare the character  $c_0$  ...  $K$   $E$   $R$  ...  $c_{n-1}$  in the pattern
- if a mismatch occurs, use the value in the table
- first, let's analyze the following cases (to determine the shift size, we look at the character that is aligned against the last character of the pattern):
  - if there is no **such character** in the pattern, we can safely shift the pattern by its entire length
  - if **the character** contained in the pattern but it is not the last one, the shift should align the rightmost occurrence of the character in the pattern with **the character** in the text
  - if **the character** equals to the last one in the pattern but there is no same character among others, we can safely shift the pattern by its entire length

# Input Enhancement

## Horspool's Algorithm

- use the pattern to make a 'Bad Match Table' that stores shift sizes of all possible characters
- compare the character  $c_0$  ...  $K$   $E$   $R$  ...  $c_{n-1}$  in the pattern
- if a mismatch occurs, look up the value in the table
- first, let's look at the character that is aligned against the last character of the pattern):
  - if there is no **such character** in the pattern, we can safely shift the pattern by its entire length
  - if **the character** contained in the pattern but it is not the last one, the shift should align the rightmost occurrence of the character in the pattern with **the character** in the text
  - if **the character** equals to the last one in the pattern but there is no same character among others, we can safely shift the pattern by its entire length

# Input Enhancement

# Pre-Structuring

## Hashing

- a very efficient way of implementing dictionaries,

# Pre-Structuring

## Hashing

- a very efficient way of implementing dictionaries,

- a dictionary is an abstract data type supporting three operations : searching, insertion, and deletion.
- elements in a dictionary can be of an arbitrary nature: numbers, characters strings of some alphabet, etc.
- each element consists of a number of fields so that each of them keeps a particular type of information
- at least one of fields corresponds to 'key', used to identify the elements dictionaries

# Pre-Structuring

## Hashing

- a very efficient way of implementing dictionaries
- distributes the elements based their keys among a one-dimensional array  $H[0,m-1]$ , called **Hash Table**

# Pre-Structuring

## Hashing

- a very efficient way of implementing dictionaries
- distributes the elements based their keys among a one-dimensional array  $H[0,m-1]$ , called **Hash Table**
- distribution performed through a function, called **hash function**,

# Pre-Structuring

## Hashing

- a very efficient way of implementing dictionaries
- distributes the elements based their keys among a one-dimensional array  $H[0,m-1]$ , called **Hash Table**
- distribution performed through a function, called **hash function**, that maps keys of the elements (large data sets) to some value (smaller data set) in  $[0,m-1]$ , called **hash address**

# Pre-Structuring

## Hashing

- a very efficient way of implementing dictionaries
- distributes the elements based their keys among a one-dimensional array  $H[0,m-1]$ , called **Hash Table**
- distribution performed through a function, called **hash function**, that maps keys of the elements (large data sets) to some value (smaller data set) in  $[0,m-1]$ , called **hash address**
- the operations 'searching, insertion, and deletion' take constant time in average (when hash table properly implemented)

# Pre-Structuring

## Hash Function

- A hash table is an array  $H[0, m-1]$

# Pre-Structuring

## Hash Function

- A hash table is an array  $H[0, m-1]$
- A hash function  $h$  then

$$h : U \rightarrow \{0, 1, \dots, m-1\}$$

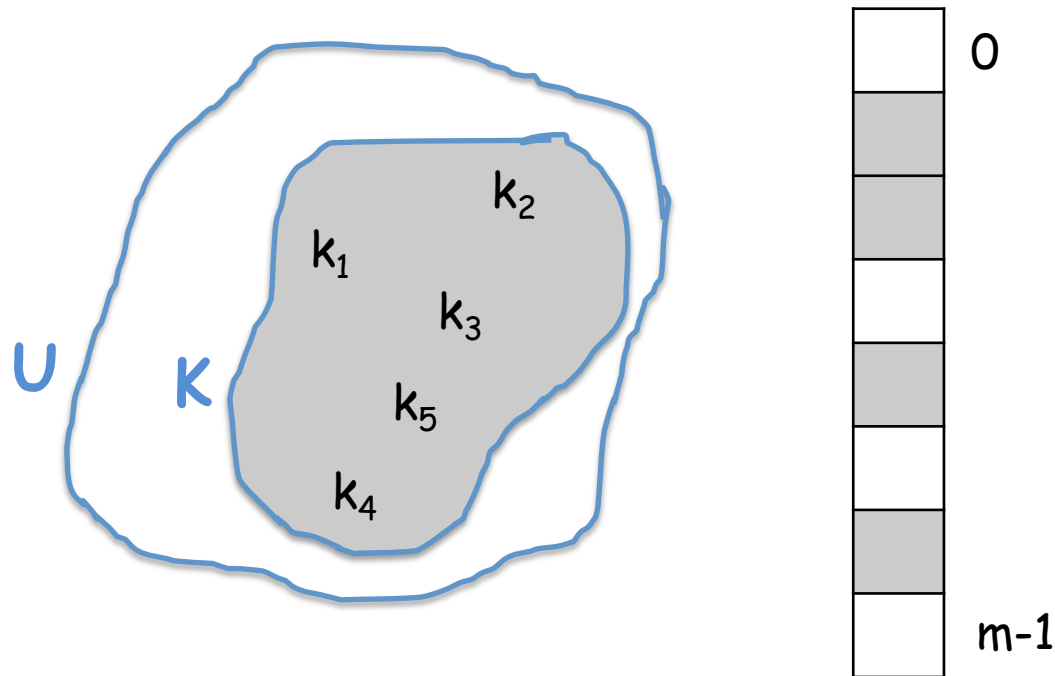

( an item  $x$  hashes to the slot  $H[h(x)]$  )

# Pre-Structuring

## Hash Function

- A hash table is an array  $H[0, m-1]$
- A hash function  $h$  then

$h : U \rightarrow \{0, 1, \dots, m-1\}$   
( an item  $x$  hashes to the slot  $H[h(x)]$  )

# Pre-Structuring

## Hash Function

- A hash table is an array  $H[0, m-1]$
- A hash function  $h$  then

$h : U \rightarrow \{0, 1, \dots, m-1\}$   
( an item  $x$  hashes to the slot  $H[h(x)]$  )

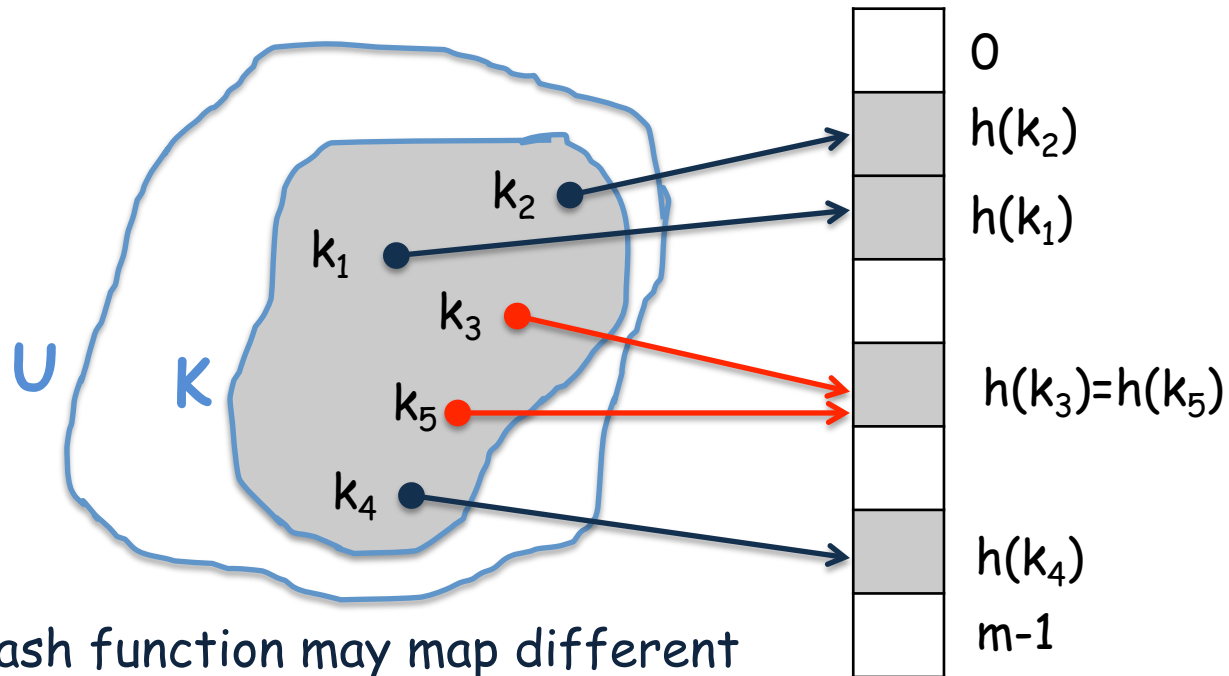

# Pre-Structuring

## Hash Function

- A hash table is an array  $H[0, m-1]$
- A hash function  $h$  then

$h : U \rightarrow \{0, 1, \dots, m-1\}$   
( an item  $x$  hashes to the slot  $H[h(x)]$  )

- **Collusion** : a hash function may map different keys to same slot (many-to-one mapping)

# Pre-Structuring

## Hash Function

- A hash table is an array  $H[0, m-1]$
- A hash function  $h$  then

$$h : U \rightarrow \{0, 1, \dots, m-1\}$$

( an item  $x$  hashes to the slot  $H[h(x)]$  )

# Pre-Structuring

## Hash Function

- A hash table is an array  $H[0, m-1]$
- A hash function  $h$  then

$$h : U \rightarrow \{0, 1, \dots, m-1\}$$

( an item  $x$  hashes to the slot  $H[h(x)]$  )

- A good hash function should :
  - be a easy to compute
  - distribute the keys evenly through the hash table
  - avoid collisions as much as possible
  - use less space (or slots)

# Pre-Structuring

## Open Hashing (Separate Chaining)

# Pre-Structuring

## Open Hashing (Separate Chaining)

each hash-table slot  $H[i]$  contains a linked list of all the keys whose hash value is  $i$

# Pre-Structuring

## Open Hashing (Separate Chaining)

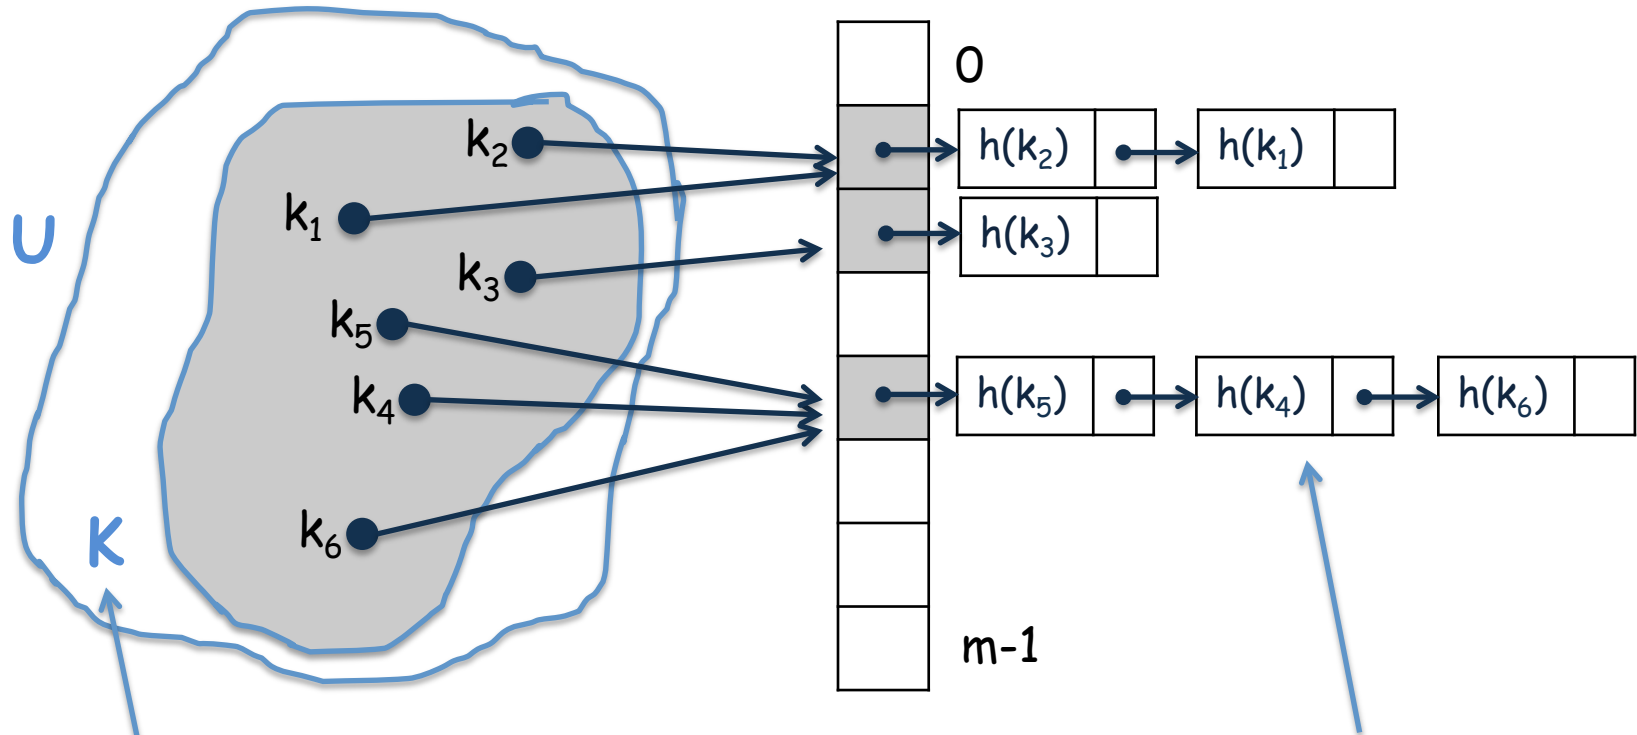

$N$  keys to be stored and  $m$  slots in hash table; average list length is  $N/m$  (this fraction is called load factor)

each hash-table slot  $H[i]$  contains a linked list of all the keys whose hash value is  $i$

# Pre-Structuring

## Open Hashing (Separate Chaining)

$N$  keys to be stored and  $m$  slots in hash table; average list length is  $N/m$  (this fraction is called load factor)  
worst case?

each hash-table slot  $H[i]$  contains a linked list of all the keys whose hash value is  $i$

# Pre-Structuring

## Open Hashing (Separate Chaining)

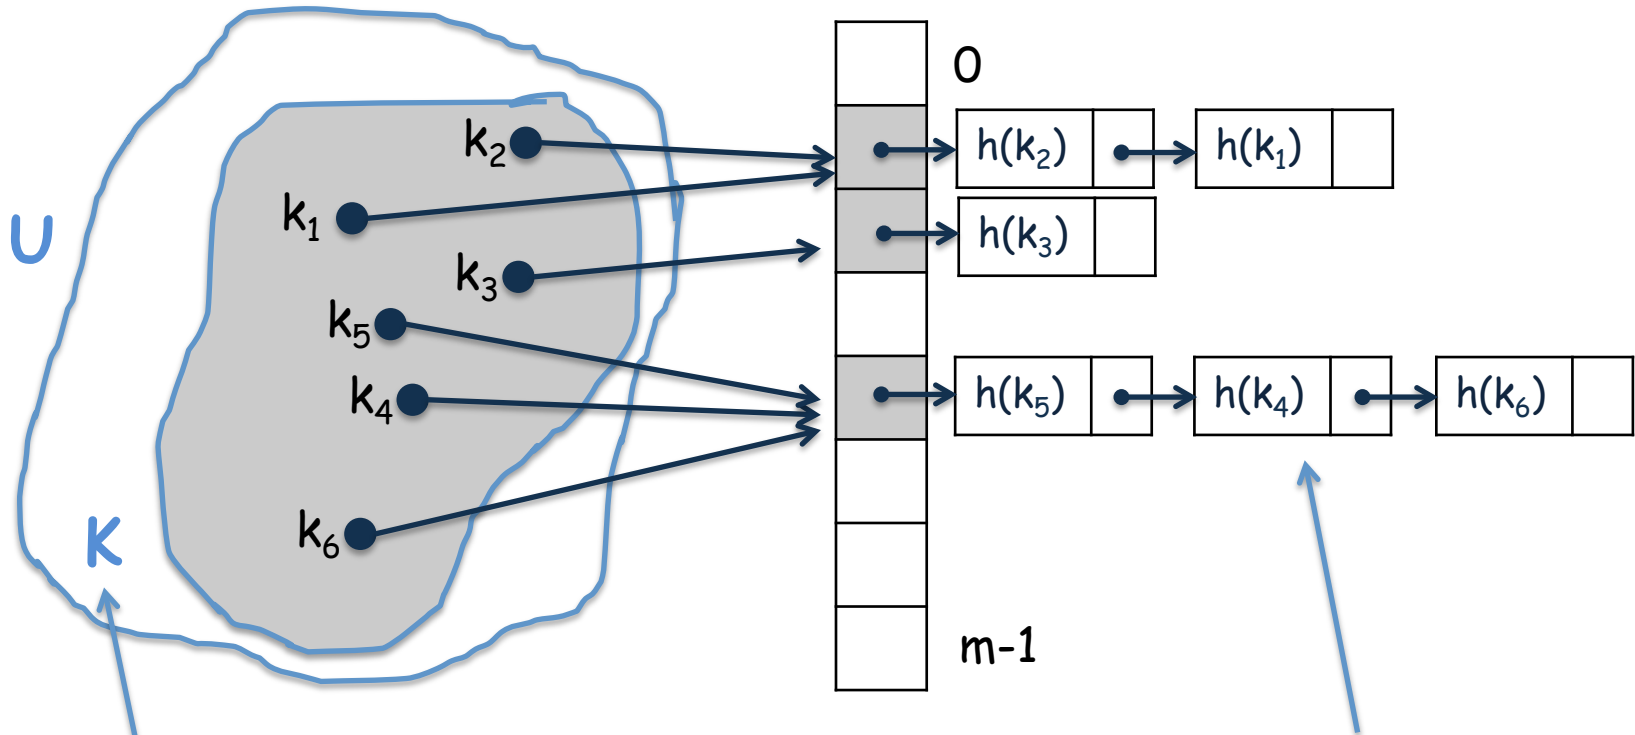

$N$  keys to be stored and  $m$  slots in hash table; average list length is  $N/m$  (this fraction is called load factor)

each hash-table slot  $H[i]$  contains a linked list of all the keys whose hash value is  $i$

$m$  is too large  $\rightarrow$  too many empty arrays entry

# Pre-Structuring

## Open Hashing (Separate Chaining)

$N$  keys to be stored and  $m$  slots in hash table; average list length is  $N/m$  (this fraction is called load factor)

each hash-table slot  $H[i]$  contains a linked list of all the keys whose hash value is  $i$

- $m$  is too large  $\rightarrow$  too many empty array entries
- $m$  is too small  $\rightarrow$  list will be too long

# Pre-Structuring

## Open Hashing (Separate Chaining)

Consider the following example :

A            FOOL            ARE            SOON

# Pre-Structuring

## Open Hashing (Separate Chaining)

Consider the following example :

A            FOOL            ARE            SOON

- Let's define a hash function as : add the positions of the letters in the alphabet and compute the remainder of the division of the sum by 13

# Pre-Structuring

## Open Hashing (Separate Chaining)

Consider the following example :

A            FOOL            ARE            SOON

- Let's define a hash function as : add the positions of the letters in the alphabet and compute the remainder of the division of the sum by 13
- $h(A) = 1 \bmod 13 = 1$   
 $h(FOOL) = (6 + 15 + 15 + 12) \bmod 13 = 9$   
 $h(ARE) = (1 + 18 + 5) \bmod 13 = 11$   
 $h(SOON) = (19 + 15 + 15 + 14) \bmod 13 = 11$

# Pre-Structuring

## Open Hashing (Separate Chaining)

Consider the following example :

A            FOOL            ARE            SOON

- Let's define a hash function as : add the positions of the letters in the alphabet and compute the remainder of the division of the sum by 13
- $h(A) = 1 \bmod 13 = 1$   
 $h(FOOL) = (6 + 15 + 15 + 12) \bmod 13 = 9$   
 $h(ARE) = (1 + 18 + 5) \bmod 13 = 11$   
 $h(SOON) = (19 + 15 + 15 + 14) \bmod 13 = 11$
- ARE and SOON are stored in same linked list

# Pre-Structuring

## Open Hashing (Separate Chaining)

Consider the following example :

A            FOOL            ARE            SOON

- Let's define a hash function as : add the positions of the letters in the alphabet and compute the remainder of the division of the sum by 13
- $h(A) = 1 \bmod 13 = 1$   
 $h(FOOL) = (6 + 15 + 15 + 12) \bmod 13 = 9$   
 $h(ARE) = (1 + 18 + 5) \bmod 13 = 11$   
 $h(SOON) = (19 + 15 + 15 + 14) \bmod 13 = 11$
- ARE and SOON are stored in same linked list
- How do we search in the hash table?

# Pre-Structuring

## Open Hashing (Separate Chaining)

Consider the following example :

A            FOOL            ARE            SOON

- Let's define a hash function as : add the positions of the letters in the alphabet and compute the remainder of the division of the sum by 13
- $h(A) = 1 \bmod 13 = 1$   
 $h(FOOL) = (6 + 15 + 15 + 12) \bmod 13 = 9$   
 $h(ARE) = (1 + 18 + 5) \bmod 13 = 11$   
 $h(SOON) = (19 + 15 + 15 + 14) \bmod 13 = 11$
- ARE and SOON are stored in same linked list
- How do we search in the hash table?
  - search whether the table contains KID or not
  - compute  $h(KID) = 11$
  - search corresponding linked-list which includes ARE and SOON

# Pre-Structuring

## Open Hashing (Separate Chaining)

Consider the following example :

A            FOOL            ARE            SOON

- Let's define a hash function as : add the positions of the letters in the alphabet and compute the remainder of the division of the sum by 13
- $h(A) = 1 \bmod 13 = 1$   
 $h(FOOL) = (6 + 15 + 15 + 12) \bmod 13 = 9$   
 $h(ARE) = (1 + 18 + 5) \bmod 13 = 11$   
 $h(SOON) = (19 + 15 + 15 + 14) \bmod 13 = 11$
- ARE and SOON are stored in same linked list
- How do we search in the hash table?
  - search whether the table contains KID or not
  - compute  $h(KID) = 11$
  - search corresponding linked-list which includes ARE and SOON
- In Separate Chaining, a search takes  $O(1+\pi)$  time in average  $\pi = N/m$

# Pre-Structuring

## Open Hashing (Separate Chaining)

Consider the following example :

A            FOOL            ARE            SOON

- Let's define a hash function as : add the positions of the letters in the alphabet and compute the remainder of the division of the sum by 13
- $h(A) = 1 \bmod 13 = 1$   
 $h(FOOL) = (6 + 15 + 15 + 12) \bmod 13 = 9$   
 $h(ARE) = (1 + 18 + 5) \bmod 13 = 11$   
 $h(SOON) = (19 + 15 + 15 + 14) \bmod 13 = 11$
- ARE and SOON are stored in same linked list
- How do we search in the hash table?
  - search whether the table contains KID or not
  - compute  $h(KID) = 11$
  - search corresponding linked-list which includes ARE and SOON
- In Separate Chaining, a search takes  $O(1+\pi)$  time in average  $\pi = N/m$
- the average number of cells examined in a successful search,  $S$  ( $U$  for unseccessful) :  $S \approx 1 + \pi/2$  and  $U \approx \pi$
