(P) Provisional value (PP) Proposed value

NITRATE AND NITRITE

- Nitrite concentrations in freshwaters are usually very low, and rarely higher than $1 \text{ mg l}^{-1} \text{ NO}_2\text{-N}$.
- High nitrite concentrations are generally indicative of industrial effluents and are often associated with unsatisfactory microbiological quality of water.

NITRATE AND NITRITE

- Determination of nitrate plus nitrite in surface waters gives a general indication of the nutrient status and level of organic pollution.
- These species are included in most basic water quality surveys and multipurpose or background monitoring programmes, and are specifically included in programmes monitoring the impact of organic or relevant industrial inputs.

NITRATE AND NITRITE

- As a result of the potential health risk of high levels of nitrate, it is also measured in drinking water sources. However, as little nitrate is removed during the normal processes for drinking water treatment, the treated drinking water should also be analysed when nitrate concentrations are high in the source water.

ORGANIC NITROGEN

- Organic nitrogen consists mainly of protein substances and the product of their biochemical transformations.
- Organic nitrogen is naturally subject to the seasonal fluctuations of the biological community because it is mainly formed in water by phytoplankton and bacteria, and cycled within the food chain. Increased concentrations of organic nitrogen could indicate pollution of a water body.

ORGANIC NITROGEN

- Organic nitrogen is usually determined using the Kjeldahl method which gives total ammonia nitrogen plus total organic nitrogen (Kjeldahl N).
- The difference between the total nitrogen and the inorganic forms gives the total organic nitrogen content.
