In the production of a drug having a molecular weight of $192 \mathbf{~ k g} / \mathbf{k m o l}$, the exit stream from the reactor flows at a rate of $\mathbf{1 0 . 5} \mathrm{L} / \mathrm{min}$. The drug concentration is $\mathbf{4 1 . 2 \%}$ (in water), and the specific gravity of the solution is 1.024 . Calculate;
a) the concentration of the drug (in $\mathbf{k g} / \mathrm{L}$ ) in the exit stream, (Hint: assume that the amount of the total solution in the exit stream is 100 kg )
b) and the flow rate of the drug in $\mathbf{k g ~ m o l} / \mathrm{min}$.

Total exit stream amount 100 kg solution
Density of drug solution:

$$
\begin{gathered}
S G_{\text {solution }}=1.024=\frac{\rho_{\text {solution }}}{\rho_{\text {water }}} \\
\Rightarrow \rho_{\text {solution }}=1000 \frac{\mathrm{~kg}}{\mathrm{~m}^{3}} \cdot 1.024=1024 \frac{\mathrm{~kg}}{\mathrm{~m}^{3}}
\end{gathered}
$$

The solution at the reactor exit contains \% 41.2 (41.2 wt \%) water by weight; Hence, there is 41.2 kg water and 58.8 kg drug in the solution.

Drug concentration in the drug solution

$$
1024 \frac{\mathrm{~kg} \text { solution }}{\mathrm{m}^{3}} \cdot \frac{58.8 \mathrm{~kg} \mathrm{drug}}{100 \mathrm{~kg} \text { solution }} \cdot \frac{1 \mathrm{~m}^{3}}{1000 \mathrm{~L}}=0.602 \frac{\mathrm{~kg} \mathrm{drug}}{\mathrm{~L} \mathrm{solution}}
$$

Molar flow rate;

$$
\dot{n}=10.5 \frac{L \text { solution }}{\min } \cdot 0.602 \frac{\mathrm{~kg} \mathrm{drug}}{L \text { solution }} \cdot \frac{1 \mathrm{kmol} \mathrm{drug}}{192 \mathrm{~kg} \mathrm{drug}}=0.033 \frac{\mathrm{kmol} \mathrm{ilac}}{\min }
$$
