

ENCEPHALON - BRAIN

- **Encephalon: (Gr.– en+kephalos): Within the head
(in + head)**

- The brain is a part of CNS that enclosed within the skull and continuous with the spinal cord.
- It is the highest control center and the most complex organ of the body in all vertebrates.
- It consists of neurons and glia cells
- It collects the information from sense organs, processes this raw data, combines the processed sensory information with memory of past circumstances and generates motor response patterns that are suited to maximize the welfare of the animal.

Shape and Size of Brain

- The shape and size of the brain varies greatly between species.
 - Brain size is sometimes measured by weight and sometimes by volume.
 - Average adult brain volume of 1300 cm³ for men and 1150 cm³ for women
 - Average adult brain weight of 1400 g for men and 1200 g for women
-

Brain Size - Intelligence ?

- Is a bigger brain a cleverer brain? Is it true?**
 - Women's brains are 9% smaller than men's on average.**
 - Human brain is 60% smaller than elephant brain.**

 - It was once thought that having a bigger brain makes you more clever, but that isn't true !!!**
-

Brain Size - Intelligence ?

- Second Hypothesis !!! Relative brain size (brain to body weight ratio)?
- It can used to be a rough estimate of the intelligence of an animal. Is it true?
- Women's BBWR are higher than Men's (1/42 – 1/50)
- Shrews have the highest BBWR of all known vertebrates

Species	Brain-Body mass ratio
shrew	1:10
small birds	1:14
Mouse	1:40
Human	1:50
cat	1:110
dog	1:125
lion	1:550
elephant	1:560
horse	1:600
shark	1:2496

Brain Size - Intelligence ?

- Third (proximate) Hypothesis !!! Number of cortical neurons and Neuron concentration?**
 - Among the mammals number of the cortical neurons can give a data for intelligence quotient (IQ)
 - If we compare the numbers individually in same species ?
 - Having more neurons should mean more cognitive capabilities ?
-

Brain Size - Intelligence ?

- **Result :** it is now recognized that the cognitive differences between species are a matter of degree. That is, they are quantitative, not qualitative, differences. Relations and connections between the neurons are the most important criteria to define intelligency.
 - **So, the size is not important for brain. Important is what you do with it?**
-

MEDULLA SPINALIS (Spinal cord)

- Spinal cord is a part of CNS. This tubular bundle tissue is located in vertebral canal, enveloped by vertebral column and covered by 3 meningeal layers.

SPINAL CORD

- The cord begins from the for. magnum of occipital bone, extends backward almost to the level of the hips and terminates with a **conus medullaris** on the lumbar region.
- The length of the cord is shorter than the length of the vertebral column. The width and ovality is also vary in sections.
- *****Intumescientia cervicalis**

Cervical enlargement

- *****Intumescientia lumbalis**

Lumbar enlargement

Segmentation of Spinal Cord

- The cord can be divided into 5 regions and numbers of segments which are equal to the vertebral bony structure.

Species	Cervical	Thoracic	Lumbar	Sacral	Caudal	Total
Dog	8	13	7	3	5	36
Cat	8	13	7	3	5	36
Cow	8	13	6	5	5	37
Horse	8	18	6	5	5	42
Pig	8	15/14	6/7	4	5	38
Human	8	12	5	5	1	31

Segmentation of Spinal Cord

- At each spinal segment, right and left pairs of spinal nerves that one on each side of the spinal cord pass through related intervertebral foramen.

Ascensus medulla spinalis

- In the fetus, vertebral segments correspond with spinal cord segments. However, because the vertebral column grows longer than the spinal cord, spinal cord segments do not correspond to vertebral segments in the adult, particularly in the lower spinal cord. For example, lumbar and sacral spinal cord segments are found between vertebral levels T9 and L2, and the spinal cord ends around the L5/L6 vertebral level, forming a structure known as the conus medullaris.
 - Cauda equina – Tail of Horse
-

Ascensus medulla spinalis

- Cauda equina**
 - conus medullaris
 - filum terminale
 - roots of sacral spinal nerves
-

Section of the Spinal Cord

- Substantia grisea – grey matter**
 - Inner «H» zone
 - Substantia alba – white matter**
 - Location of tracts
 - Canalis centralis**

Function of the Spinal Cord

- Transmission of neural signals between the brain and the rest of the body**
 - **Afferent Pathways (Ascending tracts) : Touch, pressure, temperature, pain**
 - **Efferent Pathways (Descending tracts) : Pyramidal, extrapyramidal, autonomic pathways**
- It also makes a neural circuits that can control numerous reflexes independently from brain as a central pattern generators.**
 - **Reflex arch**

Afferent pathways:
